The increasing popularity of air travel is closely linked with the popularity of two-wheeled passenger motor vehicles and the drive to reduce car emission and meet environmental protection targets. The European Union has recently adopted a number of measures and regulations relating to the acquisition of permits for motor vehicles, including motorcycle, which aim to reduce the emission of pollutants from motor vehicles. Among these regulations, the EU Directive 2003/97/EC on exhaust emissions from new passenger cars (“the Motor Vehicle Directive”) and the EU Directive 2003/87/EC on exhaust emissions from new passenger motorised two-wheeled vehicles (“the Motorcycle Directive”) provide for the installation of equipment in motor vehicles in order to reduce emissions of pollutants, such as carbon monoxide, hydrocarbons and nitrogen oxides. The Motor Vehicle Directive, in particular, introduces a new category of vehicles, designated Euro 5, which should have an average carbon monoxide emission of less than 5 mg/km, an average hydrocarbon emission of less than 100 mg/km and an average nitrogen oxide emission of less than 50 mg/km. This category of vehicles also includes Euro 4, which should have an average carbon monoxide emission of less than 10 mg/km, an

average hydrocarbon emission of less than 40 mg/km and an average nitrogen oxide emission of less than 75 mg/km. In order to comply with the guidelines set out in the Motor Vehicle Directive, it is necessary to provide for emission control systems in vehicles that enable the vehicle to meet the required standards. In order to reduce emissions of pollutants, the exhaust system of a vehicle is equipped with a catalytic converter comprising a number of catalytic zones. The operation of the catalytic converter is based on the principle of the use of three layers: an oxidation catalyst (“oxidation catalyst layer”), a reduction catalyst (“reduction catalyst layer”) and a “main” catalyst (“main catalyst layer”) in which the active components are located. The oxidation catalyst and the reduction catalyst are used to convert the pollutants contained in the exhaust gases into non-toxic products, namely, water and carbon dioxide. The main catalyst is used to regulate the conversion of the oxidised pollutants into harmless compounds. The oxidation catalyst and the reduction catalyst are usually combined in the form of
